

## ER Modelling Exercise – Hospital

Consider the following requirements for inpatients at a hospital: All patients admitted to the hospital are given a unique patient number. The patient's name, address, age, and sex are recorded. Private patients are allocated a private room, identified by the room number. Private rooms are of different types, e.g., standard, deluxe, palatial, etc. NHS patients are allocated a bed in a ward, beds being identified by the ward name and bed number. Wards are of different types, e.g., pediatric, cancer, etc, with a named sister in charge of each one. Each patient is allocated to a named consultant who supervises the medical care of the patient. The consultant decides on the treatments to be given to the patient. A treatment is any medical procedure performed on the patient. Each treatment is given a unique treatment number, and a description of the treatment and the date it is performed are recorded.

Design an E-R diagram for the above database. Derive a corresponding relational scheme from your E-R diagram.

The E-R diagram must show attributes, keys, cardinalities, and constraints. The relational scheme must be in third-normal form, with primary and foreign keys clearly indicated.

### Entity – Patient

Attributes:

- Patient\_ID
- Name
- Address
- Age
- Sex

### Entity – Private\_room

Attributes:

- Room\_number
- Room\_type

### Entity – Ward

Attributes:

- Ward\_name
- Ward\_type
- SisterInCharge

### Entity – Bed

Attributes:

- Ward\_name

- Bed\_number

## Entity – Consultant

Attributes:

- Consultant\_ID
- Name
- Specialisation

## Entity – Treatment

Attributes:

- Treatment\_ID
- Treatment\_descriptoon
- Date\_performed
